

Introduction to Machine Learning (CSCI-UA.473): Homework 2

Instructor: Sumit Chopra

October 2, 2021

Submission Instructions

You must typeset the answers using L^AT_EX and compile them into a single PDF file. Name the pdf file as: \langle Your-NetID \rangle-hw2.pdf. For the programming part of the assignment, complete the Jupyter notebook named HW2.ipynb. Create a ZIP file containing both the PDF file and the completed Jupyter notebook. Name it \langle Your-NetID \rangle-hw2.zip. Submit the ZIP file on Brightspace. The due date is October 12th, **2021**, 11:59 PM.

Theory

Question T1: Model Selection (5 points)

Consider that we are learning a logistic regression M^1 and a support vector machine M^2 , and we have partitioned the data into three subsets: D_{train} (training set), D_{val} (validation set), and D_{test} (test set). The two models are iteratively optimized on D_{train} over T steps, and now we have T logistic regression parameter configurations (i.e., weights and biases) $M_1^1, M_2^1, \dots, M_T^1$ and T support vector configurations $M_1^2, M_2^2, \dots, M_T^2$ all with different parameters. We now evaluate the expected cost for all the $2T$ models on training set, validation set, and test set. Thus we have $6T$ quantities $\mathcal{L}_{\text{train},t}^i, \mathcal{L}_{\text{val},t}^i$, and $\mathcal{L}_{\text{test},t}^i$ where $i \in \{1, 2\}$ and $t \in \{1, 2, \dots, T\}$

1. Which i and t should we pick as the best model and why? (2.5 points)
2. How should we report the generalization error of the model? (2.5 points)

Answer: Generalization error

Question T2: Gradient of Multi-Class Logistic Regression (10 points)

The loss function on a single sample (x, y) for a logistic regression model with parameters w for the multi-class classification problem can be written as

$$\mathcal{L}_w(x, y) = - \sum_{j=1}^K y_j \cdot \log p_j,$$

where K is the number of classes, y_j is the ground truth label corresponding to the j -th class for the current sample, and p_j is defined as:

$$\begin{aligned} p_j &= \sigma(w^T \cdot x)_j \\ &= \frac{e^{w_j^T \cdot x}}{\sum_{j=1}^K e^{w_j^T \cdot x}} \end{aligned}$$

The function $\sigma()$ is also called the Softmax and the loss function \mathcal{L}_w is called the cross-entropy loss: by far the most popular loss function used to solve multiclass classification tasks.

Compute the gradient of the above loss function with respect to the parameter vector w . Show all the steps of the derivation.

Question T3: Maximum Likelihood Estimate of a Gaussian Model (10 Points)

Assume you are given a dataset \mathcal{D} of n real numbers $\mathcal{D} = \{x_1, x_2, \dots, x_n\}$, where $x_i \in \mathbb{R}, \forall i$. Derive the maximum likelihood estimate of the mean μ and variance σ , of the 1-dimensional Gaussian distribution. Note that μ and σ are the learnable parameters.

1. Write down the expression of the log-likelihood $\mathcal{L}_{\mu, \sigma}(\mathcal{D})$ of the data set \mathcal{D} as a function of μ and σ . (2 points)
2. Compute the partial derivative of $\mathcal{L}_{\mu, \sigma}(\mathcal{D})$ with respect to μ , equate to zero and solve for μ . (4 points)
3. Compute the partial derivative of $\mathcal{L}_{\mu, \sigma}(\mathcal{D})$ with respect to σ , equate to zero and solve for σ . (4 points)

Question T4: Hinge loss gradients (5 points)

Unlike the Cross-Entropy loss, the Hinge loss (defined below), is not differentiable everywhere with respect to the parameters θ :

$$\mathcal{L}_{\text{Hinge}}(x, y, \theta) = \max[0, 1 - y \cdot f_{\theta}(x)],$$

for some parametric function f_{θ} . Does it mean that we cannot use a gradient-based optimization algorithm for finding a solution that minimizes the hinge loss? If not, what can we do about it?

Practicum

See the accompanying Python notebook.

Question P1: Metrics for a binary classifier (20 points)

Question P2: Support Vector Machines (50 points)
